Abstract

The effect of feeding supplementation on the nutritional characteristics of milk and cheese was studied in dairy sheep grazing on low mountain dry-grasslands during summer in typical sub-Mediterranean conditions of aridity. The control group (CG) sheep grazed on grass in these pastures, while the experimental group (EG) grazed on grass and received 600 g a day of a barley and corn mixture. Daily milk production showed a less pronounced decrease in EG than in CG (p two-tail test 0.0368). At the end of the study, the concentrations of retinol and α -tocopherol in milk and cheese from EG were higher than CG ($p < 0.05$). Supplementary feeding had a positive effect on the fatty acid composition of the sheep milk. For the first time, positive effects on the volatile composition were found in EG cheese, displaying a lower percentages of carboxylic acids associated with the pungent and rancid odor with respect to CG.

Keywords

Feeding system; feed supplementation; sheep milk and cheese; vitamins; fatty acids

Abbreviations

SFA Saturated fatty acid, MUFA monounsaturated fatty acid, PUFA polyunsaturated fatty acid, CLA conjugated linoleic acid, FA fatty acid, SPME Solid phase micro-extraction.

Chemical compounds studied in this article

Retinol (PubChem: CID 445354), α -tocopherol (PubChem: CID 14985)

Introduction

Sheep milk products can provide a profitable alternative to those from cows because of their specific taste, texture, typicity and the perception of these foods as natural and healthy. In this context, there is increased consumer interest in the nutritional composition of these products. Some major reviews have examined the biochemical composition of goat and sheep milk, which can be influenced by factors such as genetics, feeding, environment and technology (Raynal-Ljutova et al. 2008), as well as reasons for variations in composition (Jenness 1980; Remeuf et al. 1991), but little information is available on the specific molecules with nutritional properties, such as vitamins, and their variability. The importance of sheep milk to human health, its characteristics and its role in some populations have been widely demonstrated (Rubino et al. 1999; Boyazoglu and Morand-Fehr 2001; Morand-Fehr et al. 2007). In arid and poor areas where it is difficult to raise cattle and the population is at risk of malnutrition, sheep milk is a sustainable source of high quality protein and calcium. In general, consumers often consider sheep-rearing to be more ecological than cattle-rearing, and also view their products a priori as more healthy than others. The composition in macro- and micro- nutrients of milk and cheese depends on the main production factors of the farming system: genotype, reproduction, agro-climatic conditions, and farming methods such as milking and feeding (Morand-Fehr et al. 2007). The literature offers abundant information on the factors influencing the composition of cow milk, the most important of which appears to be feeding (Agabriel et al. 1995; Agabriel et al. 2001; Morand-Fehr et al. 2007) as it is the factor the masters easily chose and whose results can be quickly appreciated. One feeding study compared the fat content of goat milk from animals kept outdoors and nourished exclusively by grazing, and that of animals kept indoors and provided a concentrate supply: the fat content in milk from the outdoor group was lower than that of the indoor group (2.99% vs 2.77%) (Min et

1
2
3 al. 2005). However, in an earlier study, the opposite was found to be the case (2.9% vs
4
5 3.1% and 4.05% vs 4.52%) (Pizzoferrato et al. 2000). In sheep, the fat content of milk from
6
7 ewes that live and are fed indoors with hay, silage and concentrate (7.24%) is usually
8
9 higher than that from ewes that graze/spend their days outdoors, grazing on open pasture
10
11 (6.98%) (Pirisi et al. 2001). Feeding studies have also focused on the protein content in
12
13 milk. Protein content in milk is more stable than fat content and it is less influenced by
14
15 changes in feeding than is fat content and this is true also for lactose (Morand-Fehr et al.
16
17 2007). A feeding study on goats reported that the contents in α -tocopherol and retinol
18
19 (Vitamin A) are higher (often significantly) in milk from goats reared on pasture system
20
21 than those kept indoors, a result often reported also for cows (Coulon et al. 2003). This
22
23 situation holds even when concentrate feed is distributed *ad libitum* in addition to a pasture
24
25 diet (Pizzoferrato et al. 2000). Unfortunately, similar information for sheep is lacking. A
26
27 feeding study focused on fatty acids reported that milk from goats reared on pasture had
28
29 higher contents in C18 fatty acids, particularly polyunsaturated fatty acids (Sanz
30
31 Sampelayo et al. 2007), and noted that this composition was highly influenced by the
32
33 ingested feeds. Summarising, the main components of goat and sheep milk appear to be
34
35 less influenced by the type of farming system (indoors vs outdoors) than by the feeding
36
37 system (pasture alone vs pasture plus feed supplements) (Morand-Fehr et al. 2007).
38
39

40
41 For cheese, less information is available in the literature, and the task is more complicated
42
43 because of the variability in milk composition itself and in the cheese making process.
44
45

46
47 Stakeholders in semi-extensive farming systems in the Mediterranean mountain ranges are
48
49 concerned about forecasts of increased aridity due to climate changes (Giorgi and Lionello
50
51 2008), as it worsens the forage feed value and lessens the availability of aboveground
52
53 phytomass, thus making these farming system less sustainable (Nardone et al. 2010;
54
55 Scocco et al. 2016a). Moreover, these changes also cause modifications in the normal life
56
57
58
59
60

1
2
3 cycle of pastures, reducing the length of the time between pasture maximum flowering and
4 maximum dryness, which means that high quality pasture is available to animals for less
5 time, and thus that the well-being of the animals deteriorates (Scocco et al. 2013; Scocco et
6 al. 2016b), which in turn can affect the quantity and quality of milk and milk products.
7
8 Because of this, testing breeding system to face climate change is a key goal, especially
9 where food quality is a core value in promotion of agricultural products, as is the case of
10 Italian Apennine mountain farming systems.
11
12

13 Thus, the aim of this work was to assess the influence of feeding on the nutritional value,
14 fatty acid composition, retinol and α -tocopherol content of milk and cheese from sheep
15 reared on pasture (control group, CG) and those reared on pasture plus supplementary
16 feeding (experimental group, EG).
17
18

19 **Materials and methods**

20 *Animals, diets and experimental procedures*

21 The experiment was performed near the Natural Reserve of “Montagna di Torricchio”
22 from July 8 to August 9, 2016, in the period between the maximum flowering and the
23 maximum dryness of the pasture. After the pasture flowering peak, when the feed value of
24 the grassland is at its maximum (Scocco et al. 2016a), fifty pluriparous Comisana ewes at
25 late lactation were divided in two groups (25 ewes each) balanced for milk yield and body
26 condition score (Russel et al. 1969) to guarantee the normal social behaviour of animal. All
27 ewes were housed from 7:00 pm to 8:00 am and had unlimited access to pasture for the rest
28 of the day. The control group (CG) fed on grass pasture *ad libitum* while the experimental
29 group (EG) fed on grass pasture *ad libitum* and then received 600g/day/head of equal parts
30 of barley and corn in two equal portions before and after pasture. Food supplementation
31 (performed according to the management habits of the farmer) represents an easy and less
32 expensive farmer management action that could be able to buffer the negative effects of

drought stress on the animal productivity. This type of supplementation was chosen according to the farmer, because it is usually adopted when there are some problems in the animal feed, so it doesn't represent an additional management weigh. The chemical composition of this supplement is reported in **Table 1S (Supplementary Materials)**. Feed supplements is mainly constituted by starch (57%), protein (10%), crude fibre (3.7%), fat (3%) and free sugars (2.1%) (Mercati et al. 2018). It contains also retinol, α -tocopherol and fatty acids (**Table 1S**). Animals had access to water twice a day, morning and evening. All husbandry and experimental procedures were approved by the institutional ethics committee and the Italian Ministry of Health (No. of approval 95/2018-PR).

Chemicals and reagents

Retinol ($C_{20}H_{30}O$, molecular weight 286.46, 95% minimum, CAS No. 68-26-8) and α -tocopherol ($C_{29}H_{50}O_2$, molecular weight 430.72, >96% HPLC, CAS No. 10191-41-0) were supplied by Sigma–Aldrich (Milano, Italy). Individual stock solutions were prepared by dissolving 10 mg of pure standard in 10 ml acetonitrile. HPLC-grade methanol, ethanol, *i*-propanol, acetonitrile, *n*-hexane, chloroform and ethyl acetate were supplied by Sigma-Aldrich (Milano, Italy), while deionized water (> 18 M Ω cm resistivity) was obtained from the Milli-Q SP Reagent Water System (Millipore, Bedford, MA, USA). All the solvents and solutions were filtered through a 0.45- μ m PTFE filter from Supelco (Bellefonte, PA, USA) before use. Potassium hydroxide, and sodium chloride analytical reagents were purchased from PROLABO VWR (Milano, Italy). L-(+)-Ascorbic acid 99% and anhydrous sodium sulphate were purchased from Sigma-Aldrich (Milano, Italy). The solid-phase microextraction (SPME) fiber assembly used (Supelco, Bellefonte, PA) was Divinylbenzene/Carboxen/Polydimethylsiloxane (DVB/CAR/PDMS) 50/30 μ m.

Nutritional composition of milk and cheese

1
2
3 Ewes were machine-milked twice daily and milk samples were individually collected from
4 all the animals from each group on July 8, 13, 21, 27 and August 9, 2016 in order to
5 analyze the chemical composition (casein, fat, lactose, protein and urea) using a MilkoScan
6 6000 (Foss Electric, Hillerød, Denmark; Biggs, 1978) and the somatic cells/mL
7 (Fossomatic 5000; Foss Electric, Hillerød, Denmark). Milk yield was recorded for each
8 ewe, and the total amount of milk produced by the two groups at the morning milking was
9 noted. A traditional cheese-making technique was used to make Pecorino cheese from bulk
10 milk samples collected from the two groups at the beginning and at the end of the
11 experimental period. Raw milk from each group were collected and were heated to 37 °C,
12 and calf rennet was added to curdle the milk. After the milk had clotted, the curd was cut to
13 the size of little maize grains. The curd was cooked at 42 °C for 5 min and, after being
14 removed from the vat, was pressed into 14 cm diameter perforated cylindrical moulds in
15 order to drain the whey. Cheeses were treated with dry fine salt for 24 h and then
16 transferred to a conditioned ripening room where they remained at a temperature of 12 ± 1
17 °C and a relative humidity of 80-85% for 30 days. 6 cheeses samples were obtained per
18 process in each group and were analysed for moisture content by the AOAC (2000)
19 method 934.01 and for ash content using the muffle furnace method 935.42 (AOAC,
20 2000). The fat content of cheese samples was determined by the Mojonnier method 995.19
21 (AOAC, 2000) and the total nitrogen was determined by the Kjeldahl method 991.20
22 (AOAC, 2000) while protein content was obtained by multiplying total N by a factor of
23 6.38.

Retinol and α -tocopherol extraction and analyses in milk and cheese by HPLC-DAD

24
25
26 Samples were extracted following a slightly modified method, (Fávaro et al. 2003). One ml
27 of a solution of NaCl 1% (w/v), 0.05 g of ascorbic acid, 9 ml of ethanol, 2 ml of a KOH
28 solution (10 g KOH in 10 ml water) and 3 ml of sheep milk (or in the case of cheese, 3 g)

1
2
3 were placed in a tapered tube. In order to obtain a better dispersion of the homogenate, 4–6
4 ml of NaCl 1% were added. Alkaline digestion was performed in a water bath at 65 °C for
5 45 min with stirring (90 min for cheese samples). Tubes were cooled in an ice bath and 15
6 ml of NaCl 1% were added. Vitamin A and α -tocopherol were extracted with three 6 ml
7 portions each (9 ml for cheese) of hexane. The organic phase was evaporated under
8 nitrogen and the residues dissolved in 1 ml of acetonitrile. The volume of the supernatant
9 was recorded and an aliquot was filtered through a 0.45 μ m PTFE membrane filter and
10 injected into an HPLC-DAD system. HPLC-DAD studies were performed using an Agilent
11 1100 series (Santa Clara, CA, USA), made of an autosampler, a quaternary solvent pump,
12 with a diode-array detector (DAD). The separation was achieved on a Chromolith RP-18e
13 analytical column (100 x 3 mm I.D., macropore size 2 μ m, mesopore size 13nm) from
14 Merck (Darmstadt, Germany). The mobile phase for HPLC-DAD was: (A) acetonitrile
15 90% (B) *i*-propanol 10%, flowing at 0.8 ml min⁻¹ in isocratic conditions for a total run time
16 of only 3 minutes. The column temperature was set at 40°C and the injection volume was
17 50 μ L. HPLC/DAD analyses were performed monitoring the wavelength of 292 nm for α -
18 tocopherol and 326 nm for retinol.

41 ***Determination of fatty acids composition in milk and cheese samples by gas***
42 ***chromatography coupled with flame ionization detection (GC-FID)***

43
44
45
46 Eight ml of chloroform-methanol 2:1 (v/v) were added to an aliquot of 2 ml of milk and
47 the mixture was mechanically shaken for 10 min. After centrifugation, the lower phase was
48 collected and then 8 ml of chloroform-methanol 2:1 (v/v) was added and the same
49 procedure was repeated. The organic phase was washed with 3 ml 0.73% w/v NaCl
50 aqueous solution. Afterwards, the organic phase was siphoned, dried over anhydrous
51 sodium sulfate anhydrous, filtered, and dried under reduced pressure with a rotary
52 evaporator. The lipid extract was weighted and aliquot subjected to transmethylation.
53
54
55
56
57
58
59
60

1
2
3 Ninety ml of chloroform-methanol 2:1 (v/v) were added to 5 g of ground cheese in a 250
4 ml beaker and the mixture was extracted by a homogenizer (Ultra-Turrax, IKA, Germany)
5
6
7 for 2 min and then transferred to a separatory funnel by washing the beaker walls with a
8
9 total of 10 ml solvent mixture. Twenty ml of saturated sodium chloride aqueous solution
10
11
12 were added; the two phases of the system were shaken and the organic phase was collected
13
14
15 and dried over anhydrous sodium sulphate, then filtered and stored at -20°C before the
16
17 analysis.

18
19
20 Transmethylation following Ichihara's procedure (Ichihara et al. 1996) was performed on
21
22 each lipid extract. Briefly, a quantity of approximately 5 mg of lipid extract, dissolved in 1
23
24 ml hexane, was added to 0.1 ml of 2 M methanolic KOH and vortexed for 2 min. Then, 1.5
25
26 ml of 0.15 M aqueous acetic acid were added and the solution was vortexed for 1 min and
27
28 centrifuged at 5000 rpm for 10 min. The upper phase was transferred while 1 ml hexane
29
30 was added to the remaining one, which was then vigorously shaken and centrifuged at
31
32 5000 rpm for 5 min. This operation was repeated three times. Traces of water in the total
33
34 hexane phase were removed with anhydrous sodium sulphate. Finally, the hexane solution
35
36 containing fatty acid methyl esters (FAMES) was sealed and stored at -20°C. Before the
37
38 analysis, FAME solutions were evaporated to dryness with a nitrogen stream, dissolved in
39
40 1 ml of hexane and analysed in duplicate. The gas chromatograph used was an Agilent
41
42 Technologies 6850 equipped with a flame ionization detector (FID). The capillary
43
44 chromatographic column was a DB-225 Agilent Technologies (length 30 m, ID, 0.32 mm;
45
46 film thickness, 0.25 mm) and the injected volume was 1 µl. The split ratio was 1:30 and
47
48 the injector temperature was 260 °C. The carrier gas was H₂ and its initial flow was 3.7 ml
49
50 min⁻¹ in the column. High purity hydrogen was produced by a generator (PGH2-250 from
51
52 DBS Analytical Instruments, Vigonza, Italy). The oven temperature was programmed to
53
54 hold at 60 °C for 3 min, then increase to 220 °C at 20 °C/min, and hold at 220 °C for 8
55
56
57
58
59
60

1
2
3 min. The FID detector temperature was 260 °C (air flow 400.0 ml min⁻¹, H₂ flow 40.0 ml
4
5 min⁻¹). Each analysis took 19 min. Identifications were done by analysing the standards
6
7 (Supelco 37 Component FAME Mix) and conjugated linoleic acid methyl esters purchased
8
9 from Supelco (Bellefonte, PA, USA) and Sigma-Aldrich (Milan, Italy), by GC-mass
10
11 spectrometry (MS).
12
13

14 15 *Analysis of volatile fraction by SPME-GC-MS*

16
17 One gram of cheese was placed in a 10-ml vial and the sample was stirred for 20 min at 50
18
19 °C to accelerate equilibrium of headspace volatile compounds between the cheese matrix
20
21 and the headspace. Then, extraction of volatile compounds was carried out by injecting a
22
23 50/30 µm divinylbenzene/carboxen/polydimethylsiloxane SPME fibre (Supelco,
24
25 Bellefonte, PA) into the vial and exposing it to the headspace for 20 min at 50 °C. After
26
27 extraction, samples were directly desorbed into the injection port of the GC which was at
28
29 260 °C. A gas chromatograph equipped with mass selective detector (GC-MSD) (Agilent,
30
31 Santa Clara, CA; Agilent 6890N with Agilent 5973N) was used. Separation was performed
32
33 on an DB-WAX MS column (60 m, 0.25mm i.d., 0.25 µm film thickness). An Agilent
34
35 Chem workstation was used with the GC-MS system. The flow rate (He) was 1 ml min⁻¹
36
37 under splitless mode. The injector temperature was 260 °C. The column temperature
38
39 program was from 35°C (4 min) to 120 °C at 2.5°C min⁻¹, then from 120°C to 250 °C at
40
41 15°C min⁻¹. Total run time was 50 min. Data were acquired in the electron impact (EI)
42
43 mode with an ionization voltage of 70 eV, using scan ion monitoring (SCAN mode). Data
44
45 were analysed by using MSD Chem Station software (Agilent, Version G1701DA
46
47 D.01.00). The results from the HS-SPMEGC-MS analysis of volatile components extracted
48
49 by the SPME fibre were expressed as percentages, obtained by dividing the area of each
50
51 component by the total area of all isolated components under the conditions described
52
53 above. *n*-Alkanes (Sigma R-8769) were analysed under the same conditions to calculate
54
55
56
57
58
59
60

1
2
3 retention indices (RI) for the volatile compounds. The compounds were identified by three
4
5 comparisons: with commercial reference compounds provided by Sigma–Aldrich (St.
6
7 Louis, MO); by comparing their RI with those described in the literature; and their mass
8
9 spectra with those contained in the NIST08 and WILEY 275 libraries.

12 ***Statistical elaborations***

14
15 Linear models were performed using the *lm* function (stats R-package, version 3.4.1; R
16
17 Foundation for Statistical Computing, Vienna, Austria <http://www.R-project.org>) to assess
18
19 the effect of treatment (categorical variable) and observation time during the
20
21 experimentation (ordered factor), on retinol and α -tocopherol, also accounting for possible
22
23 interactions between the two predictors. Response variables were log-transformed to meet
24
25 model linearity assumptions. We checked the linearity assumptions using the *gvlma* R
26
27 package (*gvlma* function). Each model was subjected to backward selection of the
28
29 independent variables using the step function (stats R-package), based on calculation of
30
31 AIC values, to obtain the minimum adequate model. The significance of models' slopes
32
33 was tested using the *F* test.¹

38 **Results and discussion**

40 ***Milk production***

41
42 Milk samples were collected from 50 ewes, 25 animals per group. At the beginning of the
43
44 trial (July 8, 2016), CG sheep produced a total of 14.7 L/day of milk while the EG sheep
45
46 yielded 15.3 L/day (P two tail test equal to 0.7898), and thus there were no significant
47
48 differences before the start of the feed supplementation experiment. Halfway through the
49
50 experiment (July 21, 2016), CG sheep produced a total of 6.7 L/day of milk while the EG
51
52 sheep gave 12 L/day (P two tail test 0.0013). At the end of the trial (August 9, 2016), CG
53
54 sheep produced a total of 6.15 L/day of milk while the EG sheep produced 9.6 L/day (P
55
56
57
58
59
60

1
2
3 two tail test 0.0368). Thus, there was a less pronounced decrease in milk production in EG
4 sheep than in CG animals, according to what observed in a related study (Scocco et al.
5 2018). As expected, we observed that feed supplementation can positively affect milk
6 yield, a finding that was also reported by Min et al. (2005), who found that an increased
7 level of concentrate supplementation led to 22% greater milk yield.
8
9

15 *Chemical composition of milk and cheese*

16
17
18 The chemical composition of milk was assessed using 14 samples collected from a sub-
19 group composed of the same sheep randomly chosen, from the different sampling days
20 (Table 2S). Cheese chemical composition was assessed using 6 samples from respective
21 different sampling days (Table 3S).
22
23
24
25
26

27
28 At the beginning of the study (July 8, 2016), the milk samples analysed displayed a fat
29 content of 7.32 %, lactose of 4.35% and protein of 5.13% in CG and a fat content of 7.30
30 %, lactose of 4.26% and protein of 5.08% in EG. At the end of the study (August 9, 2016),
31 these levels were higher in EG milk (9.17, 4.19 and 6.17%, respectively) than in CG milk
32 (8.18, 4.08 and 5.90%, respectively) though the difference was not statistically significant
33 (Table 2S). This is consistent with the literature, which reports that usually the fat content
34 of both cow and ewe milk is less influenced by the type of farming system and more by the
35 animal diet, in particular the pasture diets supplemented with high levels of concentrates
36 (Morand-Fehr et al. 2007). The literature indicates that protein content is more stable than
37 fat content in milk (Morand-Fehr et al. 2007; Min et al. 2005) but our results pointed to
38 some small differences (not statistically significant). In this study, we confirmed that
39 changes in diet have a minimal effect on milk composition compared to milk yield (Min et
40 al. 2005).

59
60

We have obtained similar results for cheese. In fact, the cheese samples analysed at the beginning of the study (July 8, 2016) displayed a fat content of 37.87 % and protein of 26.21%, in CG. At the end of the study (August 09, 2016), these levels were higher in EG milk (40.44 and 25.95 %, for fat and protein respectively) than in CG milk (38.39 and 25.68%, respectively) but the difference was not statistically significant (**Table 3S**).

Method validation for the analysis of vitamins

Calibration curves of the analytes were constructed by injecting into the HPLC-DAD 50 μ l of standard solutions at specific concentrations for each compound, namely, retinol 0.1, 0.5, 1, 5, 10 mg l⁻¹ and α -tocopherol 0.5, 1, 5, 10, 25, 50 and 100 mg l⁻¹. The correlation coefficients (R²) of calibration curves of the analysed antioxidant compounds ranged from 0.9993 for α -tocopherol to 0.9995 for retinol. Five replicates were performed for each concentration, and the relative standard deviations (RSDs) ranged from 0.15 to 0.98% for run-to-run precision, and from 1.9 to 3.9% for day-to-day precision. The limits of detection (LODs) and the limits of quantification (LOQs) of the two compounds, expressed in mg l⁻¹ and calculated in HPLC-DAD with standard solutions, were very low: 0.01 and 0.03 for retinol, 0.06 and 0.2 for α -tocopherol, respectively. In addition, the mobile phase chosen for HPLC-DAD analyses (90% acetonitrile and 10% propanol, which is lipophilic), made it possible to analyse the two compounds in the same chromatographic step in a very short time (only 3 minutes of chromatographic run), much faster than those reported in other published methods ([Chotyakul et al. 2014](#); [Andrés et al. 2014](#)).

Analysis of retinol and α -tocopherol in milk and cheese

Table 1 shows the retinol and α -tocopherol content in milk from sheep reared on pasture (CG) and on pasture plus feed supplementation (EG) at five points during the height of the summer (July 8, 13, 21, 27 and August 9, 2016). At the beginning of the study, on July 8,

1
2
3 in the 14 CG milk samples, the average retinol levels were 0.73 mg l⁻¹ and those of α-
4 tocopherol were 1.67 mg l⁻¹, while in the 14 EG milk samples, the average retinol levels
5 were 0.74 mg l⁻¹ and the average α-tocopherol levels were 1.68 mg l⁻¹. After just few days
6
7
8 (on July 13, 2016), the levels of retinol and α-tocopherol in CG milk remained
9
10 substantially unchanged (0.72 and 1.75 mg l⁻¹, respectively), while in EG milk they
11
12 increased to 0.96 and 2.99 mg l⁻¹ respectively. Throughout the study, in the CG, the
13
14 concentration of retinol remained stable, with a value of 0.74 mg l⁻¹ at the end of the study
15
16 (August 9, 2016), while there was a slight, but not statistically significant, increase in the
17
18 level of α-tocopherol at the end of the treatment (1.92 mg l⁻¹). On the other hand, by the
19
20 end of the study, the EG milk had significantly higher contents of retinol and α-tocopherol
21
22 than the CG milk. Specifically, in the August 9, 2016 EG milk samples, the retinol
23
24 concentration had increased to 1.03 mg l⁻¹, a statistically significant ($p < 0.05$) difference
25
26 from the CG milk of the different time points, and the α-tocopherol concentration had
27
28 reached a value of 2.95 mg l⁻¹ (an increase of more than 1 mg l⁻¹), with a statistical
29
30 significance of $p < 0.01$ compared to CG.
31
32
33
34
35
36

37 Variation of retinol and α-tocopherol concentrations was significantly explained by the
38
39 interaction term between treatment and observation time, which accounted for the 38.55
40
41 and the 60.63% of variability (adj. R² values, $p = 2.67 \cdot 10^{-12}$ and $p < 2.2 \cdot 10^{-16}$, respectively)
42
43 of the log-transformed concentrations. Detailed results are reported in **Table 4S**.
44
45
46
47

48 **Figure 1** shows an overlapping of 3 HPLC-DAD chromatograms: one was from a standard
49
50 mixture solution, the second from July 8, 2016 CG milk sample, and the third from the
51
52 August 9, 2016 EG milk sample.
53
54

55 **Table 1** also shows information about cheese made from CG and EG milk ($n = 6$) at the
56
57 beginning and at the end of the study. The levels of retinol and α-tocopherol in cheese from
58
59 the beginning of the study were 1.64 and 5.02 mg kg⁻¹ in CG (July 08, 2016). These values
60

1
2
3 remained constant in the cheese sample from CG milk: at the end of the study they were
4
5 1.68 for retinol and 4.64 mg kg⁻¹ for α -tocopherol. In contrast, these values were higher in
6
7 the cheese samples made from EG milk at the end of the study: they rose to 2.02 and 5.77
8
9 mg kg⁻¹ respectively, a statistically significant difference ($p < 0.05$ for both compounds)
10
11 from the CG values. The literature provides little information about how the vitamin
12
13 content in sheep milk may change as a result of changes in feeding systems. There are
14
15 some studies on cows and some on goats. One work examined four studies on goats and
16
17 reported that the various authors found higher α -tocopherol content in milk from animals
18
19 reared on a pasture system (0.12, 0.941, 1.173 and 0.932 mg kg⁻¹) compared to milk from
20
21 goats kept indoors (0.09, 0.644, 0.97 and 0.645 mg kg⁻¹) (Galina and Haenlein 2004;
22
23 Fedele et al. 2004; Pizzoferrato et al. 2000). Only one of these studies reported that this
24
25 high α -tocopherol content in milk persisted even when animals could feed *ad libitum* on
26
27 concentrated feed in addition to the pasture diet (Pizzoferrato et al. 2000). One of these
28
29 studies on goats contradicted our findings on sheep: Fedele et al. observed that
30
31 supplementation of a pasture diet with concentrates reduced the retinol content in the milk
32
33 of these goats (Fedele et al. 2004). To sum up, in our study on feeding systems and sheep
34
35 milk and cheese, we have shown that the concentration of retinol and α -tocopherol
36
37 increased with feed supplementation ($p < 0.05$).
38

41
42
43
44

45 ***Fatty acids in sheep milk and cheese***

46
47
48 Fatty acids were determined by gas chromatography coupled with flame ionization
49
50 detection, and among them, the nineteen more abundant, well detected and well resolved
51
52 (C4:0, C6:0, C8:0, C10:0, C12:0, C13:0, C14:0, C14:1, C15:0, C16:0, C16:1, C17:0,
53
54 C17:1, C18:0, C18:1,*n*9, C18:2,*n*6, C18:3,*n*3, CLA (C18:2*c*9,*t*11), C20:0) were considered.
55
56
57 The results, in terms of individual fatty acids percentages, saturated fatty acids (SFAs),
58
59 monounsaturated fatty acids (MUFAs) and polyunsaturated fatty acids (PUFAs) classes
60

percentages, and the ratio *n6/n3* PUFAs, are provided in **Table 2**. The different diets have a clear effect on the fatty acid composition of milk fat: the EG group, fed with supplemented diet, produced higher quality milk in terms of these important nutrients. In particular, on most of the sampling days, the total SFAs % was lower in EG milk than in CG milk, even if the differences between the two groups were not statistically significant in this case. In general, the total MUFAs % was very similar in the two groups during the whole sampling period. PUFAs % was higher in the EG than the CG milk on four of the five sampling days; in particular, the difference was significant on July 21 ($p = 0.048$) and in the total ($p = 0.049$). Linolenic acid (C18:3, *n3*) %, was actually significantly higher in EG compared to CG milk in the sampling of July 21, when in fact also the ratio *n6/n3* PUFAs was lower ($p = 0.034$) in EG than in CG group. In each of the sampling day, linoleic acid was higher on average in EG than in CG and statistically significant when considering the total of the samples. The percentage of the conjugated linoleic acid (CLA, C18:2*c9*, *t11*) detected did not differ significantly between the control and experimental groups in each of the samplings and in the total; however, the average CLA % was higher in the EG on every sampling day except July 27, when it was identical in the two groups.

Fatty acid composition was assessed also in cheese produced in July before supplementation and in cheese from CG and EG produced in August with milk obtained after 1 month supplementation (**Table 3**). The most abundant fatty acid class, SFAs, was significantly higher ($p < 0.05$) in CG cheese before supplementation, with an average of 70.84%, compared to values found in the two groups after one month of supplementation (66.59% in CG and 67.24% in EG), which did not differ significantly from each other. MUFAs were found in the average range of 22.18-24.68%, PUFAs in the range of 3.73-4.15% and the *n6/n3*-PUFAs ratio in the range 0.87-1.00, and they did not significantly differ in the three groups investigated. Instead, percent content of CLA (C18:2*c9*,*t11*) was

1
2
3 significantly higher in cheeses produced in August than in cheeses produced in July. Thus,
4
5 in the case of cheese, no significant effect produced by supplementation could be observed
6
7 on the fatty acid composition. However, significant differences were found between cheese
8
9 produced in July (before supplementation) and cheese produced in August, indicating a
10
11 generally higher quality in terms of fatty acid composition, in cheeses produced in August,
12
13 having significantly lower SFAs % content and significantly higher CLA % content, as
14
15 compared to cheese produced in July.
16
17

18
19 In this regard, a study on milk from goats reared on pasture reported higher contents in
20
21 C18 fatty acids, particularly PUFAs and CLA (Sanz Sampelayo et al. 2007), a finding that
22
23 our study on sheep confirms, albeit with feed supplementation. Moreover, the observation
24
25 that cheese produced in August contained significantly higher percentages of CLA than
26
27 that produced in July is quite important, considering the antioxidative and anticarcinogenic
28
29 properties of CLA, as well as its ability to stimulate immune response and to protect
30
31 against arteriosclerosis (Mir et al. 1999).
32
33
34
35

36 *Volatile fraction in sheep cheese samples*

37
38

39 Volatile compounds identified in sheep cheese samples (n=6) investigated by SPME–GC–
40
41 MS are shown in **Table 4**. A total of 19 compounds were detected, specifically, 9
42
43 carboxylic acids, 5 esters and 5 alcohols. The chemical classes with the highest area
44
45 percentages were carboxylic acids (84.50%–89.37%), followed by esters (9.37-12.58%)
46
47 and alcohols (3.04-5.46%). The total area percentage of the identified compounds in the
48
49 samples analysed is very high, ranging from 99.39 to 99.94%.
50
51

52
53 Differences were found in the volatile compounds in the different samples. Regarding total
54
55 carboxylic acids, in CG cheeses the percentage in the July 8 sample (n°1) was 84.50%,
56
57 while a higher value was found in the August 9 sample (n°2), which contained 89.37%.
58
59 Comparing the control and experimental cheeses on August 9, there was appreciable
60

1
2
3 difference in the percentage of total carboxylic acids between cheese n°2 (89.37%) and
4 cheese n°3, which contained 81.90%. Looking at specific carboxylic acids in the CG

58
59
60

difference in the percentage of total carboxylic acids between cheese n°2 (89.37%) and cheese n°3, which contained 81.90%. Looking at specific carboxylic acids in the CG cheeses, the August 9 cheese contained higher levels of acetic acid, butanoic, octanoic and decanoic acids than July 8 cheese. However, in the August 9 EG cheese, these values were lower than or similar to those found in July 8 CG cheese and August 9 CG cheese.

Carboxylic acids can originate from three main biochemical pathways: lipolysis, proteolysis and lactose fermentation. Enzymes with lipolytic activity (esterases, lipases) may cause the release of linear-chain acids (butanoic, pentanoic, hexanoic, heptanoic, octanoic, decanoic and dodecanoic acids) (Delgado et al. 2010); instead, it is thought that acetic and propionic acids may have a microbial origin as a result of lactose fermentation, since changes in those acids have been associated with the growth of lactic acid and propionic bacteria. However, the shorter carboxylic acids can also be derived from ketones, esters and aldehydes by oxidation (Molimard and Spinnler, 1996), as the metabolic products of lactose metabolism, deamination of amino acids and possibly lipid oxidation. It is known that the above mentioned carboxylic acids are negative odourants; in fact, acetic acid is associated with a “sour-vinegar” odour (Caprioli et al. 2016), and may explain the slightly acid taste of these cheeses; butanoic, octanoic and decanoic acids, as well as others, are associated with the “pungent”, “rancid”, “sweat”, and “metal” odour qualities (Rodriguez-Campos et al. 2011; Rodriguez-Campos et al. 2012).

Differences were also found in the total esters in the different samples, but unlike the carboxylic acids, there was a decrease in the percentages of esters in the CG cheeses: the July 8 CG cheese (sample n°1) contained 10.60%, while the August 9 CG cheese (n°2) had 9.37%. Instead, comparing control and experimental cheeses, the percentages of esters increased after the month of supplementary feeding: August 9 EG cheese (sample n°3) contained 12.58%. Looking at specific esters, specifically ethyl butanoate, ethyl hexanoate

1
2
3 and ethyl octanoate, for the control group there was a drop in the percentages of these
4
5 compounds after a month: the August CG cheese contained less than the July CG cheese.
6
7 However, for the experimental group, the content in these specific esters was higher in the
8
9 August EG cheese (n°3) than in n°1 and n°3 cheeses. Esters were the second most
10
11 abundant compounds isolated in the headspace of the cheeses analysed in our study, and
12
13 due to their high amount, probably contribute to the overall flavour of cheese, as they have
14
15 low detection thresholds (Delgado et al. 2010). The decrease of these esters in the August 9
16
17 CG cheese could be explained by the increase in the carboxylic acid in this cheese, and
18
19 vice-versa. The highest percentages of esters were found in the August 9 EG cheese (n°3);
20
21 this is a positive factor, as they are associated with the pleasant odour qualities of fruit,
22
23 pineapple, apple and banana. Finally, there was a decrease in the percentages of total
24
25 alcohols in the CG cheeses. The July 8 CG cheese (n°1) contained 5.29%, while the
26
27 August 9 CG cheese (n°2) had 3.04%. Instead, comparing CG and EG cheeses, the August
28
29 9 EG cheese (sample n°3) had a higher percentage of total alcohols (5.46%) than the CG
30
31 cheeses. Alcohols are generally responsible for producing desirable flavour notes (Caprioli
32
33 et al. 2016); one of interest is 3-methylbutanol, which is associated with a malty-chocolate
34
35 odour.
36
37
38
39
40
41
42

43 **Conclusions**

44
45 This study highlights the important effects of feeding supplementation on the composition
46
47 and quality of milk and cheese from sheep grazing on dry pasture, more in terms of
48
49 specific compounds (retinol, α -tocopherol, fatty acids) and milk production than in terms
50
51 of nutritional composition. For the first time, positive effects on the volatile composition
52
53 were found in EG cheese. In fact, EG samples displayed a lower content of carboxylic acid
54
55 associated with the “pungent”, “rancid”, “sweat”, and “metal” odour with respect to CG. It
56
57 is to be hoped that our results documenting feeding-related variations in the chemical
58
59
60

1
2
3 features of milk and cheese will prove useful for those developing solutions to adapt the
4 sub-Mediterranean semi-extensive farming system to the forecasted global warming-
5 related climatic changes. Our results indicate that the expected worsening of pasture
6 features could have deleterious effects on the chemical characteristics of sheep milk
7 products. This in turn could have negative ramifications for the economic sustainability of
8 pastoral systems, which are a key part of EU policies to counter the depopulation of
9 mountain communities and the loss of biodiversity in these lands. In this perspective, the
10 enhanced nutraceutical value, due, for example, to the major anti-oxidant vitamin A and E
11 contents, could be communicated to the consumers in order to promote the farm products,
12 enhancing the farm income.

For Peer Review Only

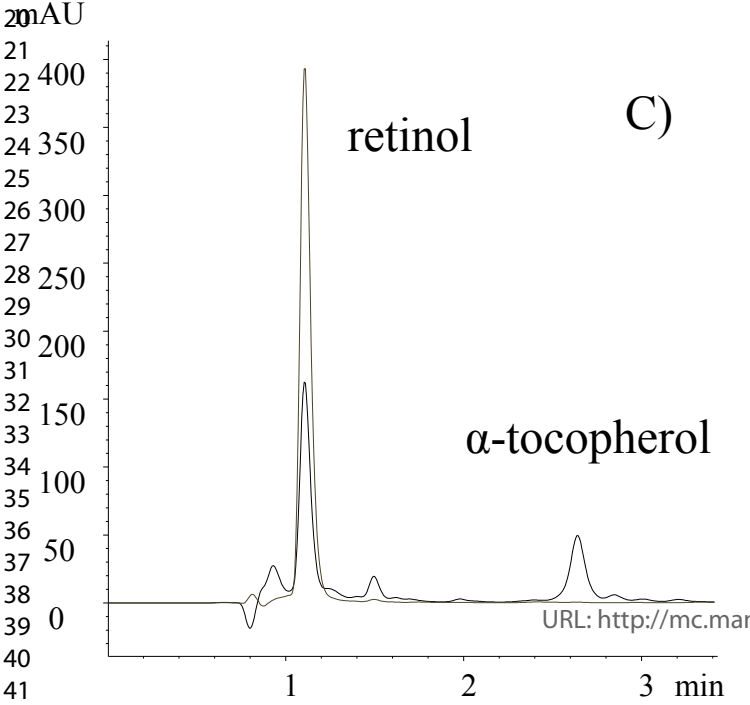

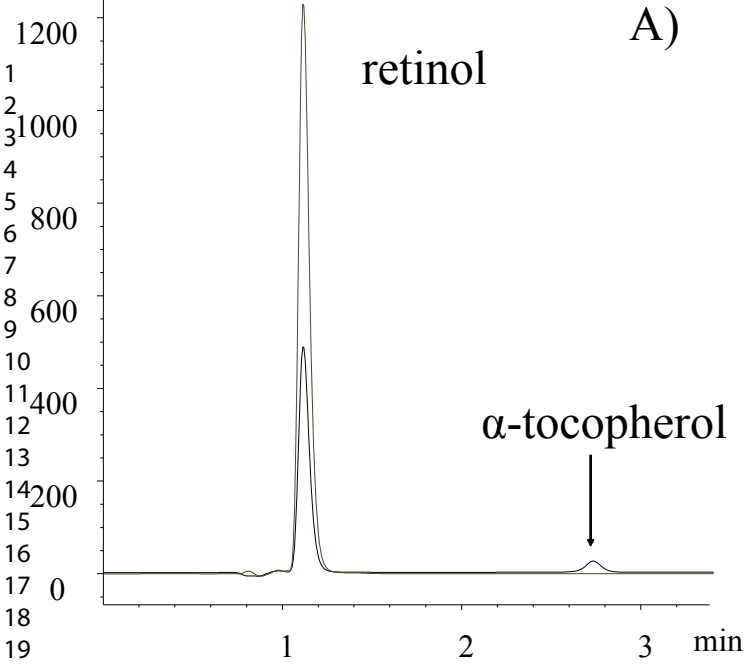

Figure 1. HPLC-DAD chromatograms reported at 326 and 292 nm for retinol and α -tocopherol respectively, corresponding to A) standard mixture solution B) milk samples from CG sheep (July 8, 2016) and C) milk samples from EG sheep (August 9, 2016).

Table 1. Retinol and α -tocopherol in milk and cheese from sheep reared on “pasture” (control group, CG) or on “pasture plus feed supplementation” (experimental group, EG) farming system (data are expressed in mg l⁻¹ for milk and in mg kg⁻¹ for cheese).

MILK time points	Group	Retinol	α -tocopherol
July 08, 2016	CG (n=14)	0.73 ^a ±0.12	1.67 ^a ±0.34
	EG (n=14)	0.74 ^a ±0.12	1.68 ^a ±0.35
July 13, 2016	CG (n=14)	0.72 ^a ±0.06	1.75 ^a ±0.56
	EG (n=14)	0.96 ^b ±0.22	2.99 ^b ±0.70
July 21, 2016	CG (n=14)	0.76 ^a ±0.06	1.94 ^a ±0.37
	EG (n=14)	0.91 ^b ±0.12	2.94 ^b ±0.31
July 27, 2016	CG (n=14)	0.76 ^a ±0.09	1.93 ^a ±0.49
	EG (n=14)	0.94 ^b ±0.18	3.01 ^b ±0.43
August 09, 2016	CG (n=14)	0.74 ^a ±0.07	1.92 ^a ±0.32
	EG (n=14)	1.03 ^b ±0.21	2.95 ^b ±0.32
CHEESE time points	Group	Retinol	α -tocopherol
July 08, 2016	CG (n=6)	1.64 ^c ±0.02	5.02 ^c ±0.16
August 09, 2016	CG (n=6)	1.68 ^c ±0.14	4.64 ^c ±0.55
	EG (n=6)	2.02 ^d ±0.13	5.77 ^d ±0.3

^{a,b} For milk different letters in the same column indicate significant differences ($p < 0.05$ for retinol) and ($p < 0.01$ for α -tocopherol) between experimental and control group.

^{c,d} For cheese different letters in the same column indicate significant differences ($p < 0.05$)

Table 2. Average fatty acid composition in milk from each sampling day and from the total, reported in terms of % saturated fatty acids (% SFAs), % monounsaturated fatty acids (MUFAs), % polyunsaturated fatty acids (PUFAs), and individual percentages of selected fatty acids: linoleic acid (C18:2,n6), linolenic acid (C18:3,n3) and conjugated linoleic acid (CLA, C18:2c9,t11). The ratio n6/n3 PUFA is also reported.

Sampling day		% SFAs		% MUFAs		% PUFAs		% C18:2,n6		% C18:3,n3		n6/n3 PUFA		CLA (C18:2 c9,t11) %

EG: experimental group (grazing plus supplemented diet), n=14; CG: control group (grazing) (n=14). SD: standard deviation; RSD: relative standard deviation. Two sampling groups within the same column are significantly different (p < 0.05, one-way ANOVA) for the parameter considered if their average values do not show superscript letters in common. Experimental group and control group within the same row are significantly different (p < 0.05, one-way ANOVA) if different superscript symbols are reported on their average values for the parameter considered.

Table 3. Average fatty acid composition in cheese at the beginning and at the end of the study, reported in terms of saturated fatty acids (SFAs), monounsaturated fatty acids (MUFAs) and polyunsaturated fatty acids (PUFAs) % composition and in terms of selected individual fatty acids % composition. The ratio *n6/n3* PUFAs is also reported.

	July 08, 2016		August 09, 2016			
	CG		CG		EG	
	% average	% RSD	% average	% RSD	% average	% RSD
